

COLOSSEUM HACKATHON IDEA · SOLANA · SEPTEMBER 2026

Matchbook

The settlement-truth layer for Solana payments:
every transfer knows its invoice.

problemStatement · technicalApproach · targetAudience · businessModel · competitiveLandscape

\$650B/month moves on Solana. Reconciling it is still manual.

On Solana, money moves at 400ms — but **bookkeeping lives in 2009**. Businesses and DAOs that pay in USDC face a problem the ecosystem itself has named:

"Businesses using crypto for accounts payable and receivable face a reconciliation problem: verifying which invoice corresponds to which on-chain transfer."

— Solana Compass, Request Network profile
(solanacompass.com/projects/request-network)

Every payroll batch, vendor payment and agent purchase ends the same way: a finance person (or a script) eyeballing memos, guessing which transfer settles which invoice — then chasing the mismatches.

6M

monthly USDC senders on Solana (Artemis, Aug 2026)

\$650B

monthly adjusted stablecoin volume, Feb 2026 — highest of any chain (Everstake/Artemis)

\$0

spent today on auto-reconciliation by the typical DAO or SMB paying in USDC — the work is spreadsheets and eyeballs

Three signals say the market is ready

1 · The incumbent left

Sablier wound down its Solana streaming product (UI claiming-only June 2026, maintenance mode July 2026). Payroll teams consolidated onto Streamflow — **24,000+ projects, \$1.6B TVL** — with no invoicing or reconciliation layer attached. (blog.sablier.com/solana-shutdown; crypto.news)

2 · The gap is acknowledged, not solved

Request Finance (EVM-origin, \$300–1,500/mo, Solana added 2024) is the only suite touching this, and its own docs name reconciliation as the unsolved core. Privacy-payroll demand proof: Request × Aleo processed **\$3.7M in weeks** of launch. (solanacompass.com/projects/request-finance)

3 · Machine payments just shipped without receipts

x402 settled 167M+ transactions by May 2026 — but real commerce is only ~\$28K/day, and the spec defines **no refunds, disputes, or receipt binding**. The x402 Foundation's ROADMAP.md is an empty placeholder. Agents paying APIs have no paper trail. (docs.x402.org; github.com/x402-foundation/x402; presenc.ai tracker)

Matchbook = Proof-of-Invoice + Auto-match + Dispute rails

① Proof-of-Invoice binding

A Token-2022 **transfer-hook program** + Pay/memo convention that embeds a canonical invoice hash into the transfer itself. The binding is enforced by the protocol at settlement time — not typed in afterwards by a bookkeeper. Impossible to do this way on EVM; native to Solana.

② Auto-match engine

An indexer that watches bound transfers and your ledger (QuickBooks/Xero export or plain CSV), then matches invoice ↔ payment ↔ payout batch in real time. Sub-second settlement on Solana means reconciliation happens *with* the payment, not weeks later. Exposed as a web app + API + webhooks.

③ Dispute & refund rails

A small escrow PDA (program-derived account) holds payment state per invoice: **partial payments, refund windows, dispute flags** — the TradFi primitives stablecoin invoicing never had. Same rails serve x402-style agent purchases that today have no recourse path.

Buildable in one hackathon — three components, all boring by design

Anchor program

Token-2022 transfer hook (Rust/Anchor): verifies invoice hash exists in a Matchbook registry PDA before allowing transfer of a configured mint. Fallback mode: Pay-protocol memo parsing for wallets that skip hooks. ~600 LOC, testable on validator locally.

Dispute PDA

Escrow account per invoice: partial-pay state machine (partial → complete → disputed → refunded). Refund = signed claim back to source; dispute = freeze + evidence hash attached. Deliberately minimal — no oracle, no court.

Indexer + matcher

Geyser/websocket stream → Postgres → deterministic matcher (invoice hash exact match first, amount+payee heuristic second, confidence score surfaced). Serves REST + webhooks.

Hackathon scope (5 days)

Day 1-2 hook program + local tests → Day 3 indexer + matcher demo → Day 4 QuickBooks CSV round-trip → Day 5 x402 receipt demo: agent buys an API call, receipt reconciles itself. All on devnet, all open source.

Agents settle in USDC but leave no paper trail

2026 shipped the rails: Pay.sh (Solana Foundation × Google Cloud, May 2026), x402 on SVM, Circle Agent Stack with \$0.000001 nanopayments. What none of them define:

- **Receipts** — a payment record a finance system (human or agent) can consume
- **Refunds/disputes** — push-based payments with zero recourse
- **Budget reconciliation** — an agent with a \$50/day mandate can't produce a matched expense log

The same three Matchbook primitives solve this.

Human AP teams and AI agents need the identical thing: settlement truth.

Skyfire — \$9.5M raised, Coinbase Ventures & a16z — **ceased operations early 2026** chasing proprietary agent identity. Lesson: the open layer everyone needs is not identity, it's the boring ledger. (archtools.dev migration post, Mar 2026)

Chainalysis counted **100M+ agentic transactions on Base** through Q1 2026 — but notes most was farming bots, real commerce ~\$28K/day. Speculation happens because real business rails don't. Receipts + disputes are what converts bot traffic into actual commerce. (chainalysis.com x402 adoption, Jun 2026)

TARGET AUDIENCE

Who feels this pain weekly

DAO ops & crypto-native companies

Streamflow's 24,000+ projects pay contributors in batches today. Their finance workflow: export CSV, match by hand, hope. Matchbook plugs in as a webhook from day one.

API businesses serving agents

MCP/x402 API sellers (Cloudflare workers, Arch Tools' 63-tool marketplace) need receipt + refund rails before serious buyers trust agent-driven spend.

Agencies & offshore teams

Stablecoin contractor pay is now mainstream — Gusto added USDC same-day contractor payouts (Mar 2026), Sphere runs recurring billing GA. Finance teams inherit the reconciliation problem at scale.

First user: me

This submission's author operates AI agents that pay for API services and would integrate Matchbook as its own expense ledger at MVP. The ideathon guide's "be user number 1" is literal here.

Priced like the spreadsheet it replaces

SaaS tiers

Free: 50 matched transfers/mo, devnet, public API.

Team \$49/mo: unlimited matching, QuickBooks/Xero sync, webhooks, dispute console.

Enterprise: custom mints, private indexer, SOC 2 track (Request Finance charges \$300–1,500/mo for the suite — room to undercut with focus).

Dispute-rail fees

0.1% on value settled through escrow PDA (refunds, partial payments, x402 receipt flows). At \$650B/mo chain volume, capturing even 0.001% of B2B flows is \$6.5M/yr run-rate.

Why this compounds

Reconciliation data is the wedge; the ledger it creates becomes the accounting system of record for stablecoin-native businesses — and the only structured expense data source for the agent economy. Data network effects: more matched payments → better heuristics → more matching.

Beachhead GTM

Streamflow + Sphere user base as distribution partners; publish the invoice-hash convention as an open standard other Solana payment tools adopt (network standard beats proprietary — the Skyfire lesson).

Everyone touches payments. Nobody owns settlement truth.

Player	What they do	What they don't do
Request Finance	Full crypto AP/AR suite, QB/Xero sync, Solana since 2024, \$1.2B volume	EVM-origin, \$300+/mo, no Solana-native binding, no agent receipts
Streamflow	Payroll streaming + batch payouts, 24k projects	No invoicing, no reconciliation, no disputes
MoonPay Commerce (ex-Helio)	Merchant checkout, \$1.5B processed, Shopify	Point-of-sale focus; leaves books to the merchant
x402 / Pay.sh / Circle Agent Stack	Machine payment rails, nanopayments	No receipts, refunds, or disputes defined — roadmap empty
GhostPay-B2B, StealthBooks	Hackathon-grade B2B tools on GitHub	Not production; confirms demand, no protocol binding

Matchbook's moat is the Solana-specific binding primitive: Token-2022 transfer hooks make invoice-binding a protocol property, not a SaaS feature — a wedge EVM-origin competitors can't retrofit without an indexer rewrite

SUMMARY

Matchbook: make every USDC transfer settle its own books

- **Problem:** named-by-the-ecosystem reconciliation gap across 6M monthly senders
- **Approach:** Token-2022 hook binding + indexer matcher + dispute PDA — shippable in a 5-day hackathon on proven primitives
- **Audience:** DAOs and agencies paying in USDC, then the agent economy
- **Business:** \$49/mo SaaS + 0.1% dispute-rail fee, open-standard convention as moat
- **Landscape:** incumbents (Request, Streamflow, x402 rails) all adjacent, none own it

Every claim in this deck traces to a primary source gathered this week: solanacompass.com, docs.x402.org, github.com/x402-foundation/x402, chainalysis.com, crypto.news, blog.sablier.com, gusto.com, solana.com, archtools.dev, everstake.one, presenc.ai, madeonsol.com.
Research compiled 2026-09-04.

Be user number 1: the author's AI agents pay for API services weekly and will run Matchbook as their expense ledger from MVP day.
